Abstract

Magnetorheological (MR) fluids alter their flow resistance as a function of the magnetic field. The variation in flow resistance is rapid and completely reversible and due to this MR fluids have been used in Braking applications. In the present paper, a MR Brake experimental setup, developed to evaluate the torque performance of MR brake, has been detailed. The measured torque values were compared with the estimated torque values and errors in the experimental values compared to theoretical torque values as a function of rotational speed have been presented. To investigate the reason for the variations, the vibration of MR disc was measured using proximity sensor. Based on the obtained results from proximity sensor the setup was modified. A comparison among the vibration signals measured on test setups (before modification and after modifications) has been presented.

Keywords: MR brake, roller bearing, vibration, torque.

1. Introduction

![Fig. 1 Asymmetric Sketch of MR Brake](image)

The MR brakes are actuated by passing the magnetic field through the magnetic particles with the help of current carrying electromagnet. On the application of magnetic field, MR fluid changes its state from liquid to semi-solid by aligning magnetic particles in chains. The formation of chain is shown in figure 2. Due to such chaining action, yield strength of fluid increases, friction between disk and housing (Fig. 1) increases and as a result the braking occurs.
Sukhwani, Hirani, (Sukhwani, Hirani, 2008) designed a MR brake for high rotational speed up to 2000 rpm. Sukhwani and Hirani (Sukhwani, Hirani, 2008) concluded that, effectiveness of MR brake reduces at high speeds due to shear thinning of MR fluid. Therefore, to make MR brake more effective at higher speed operation, one needs to think of ‘Shear stable MR fluid’. To investigate this phenomenon a MR brake test setup was developed in the laboratory. Initial study on test setup showed enormous variation between the theoretical and experimental frictional torque values. The measured experimental frictional torque values were higher than the estimated theoretical torque values, which motivated to investigate the test setup. Moreover it was observed that the one of natural frequency of the test setup was close to operational speed of rotating disk. In the present work, experimental investigation is carried out by measuring the displacement of the shaft using proximity sensor at different rotational speed of MR brake and theoretical natural frequency of the system was estimated by using Dunkerley’s method (Budynas, Nisbett, 2011). Based on the obtained results the necessary modifications have been incorporated.

2. Braking Torque

The MR brake experimental setup used for the present work is shown in figure 3. It consists of 2 HP DC motor. The speed of the motor is controlled by using the speed controller. A flywheel is mounted between the DC motor and the MR brake through bearing bracket, jaw coupling and flexible coupling. A DC power supply (30 V and 5 A) is used to control the current to the electromagnet of MR brake. The speed of the motor was measured by using tachometer. The experimental torque for the present work was calculated using the instantaneous power drawn from the motor at particular rotational speed.

The theoretical torque for the present work is estimated using following formula (Sukhwani, Hirani, 2008, Sukhwani et al 2009, Sukhwani, Hirani, 2008, Sarkar and Hirani (accepted), Sarkar.)

\[ T = 2\pi h \tau_{yd} \left( \frac{2}{5} - \frac{n_1^2}{n_2^2} \right) + 4\eta \omega \left( \frac{3}{5} - \frac{n_1^3}{n_2^3} \right) \]  

(1)

Where \( h \) is the gap between the rotor and housing filled with MR fluid, \( \tau_{yd} \) is the yield stress function of magnetic field, \( \eta \) is the viscosity of the MR fluid, \( \omega \) is angular velocity of the disk brake, \( r_2 \) is the outer radius of the disk and \( r_1 \) is the radius of the shaft as shown in figure 4.

To study the braking torque of MR brake, \( r_1=55 \) mm, \( r_2=196 \) mm and \( h=1 \) mm (parameters used to develop MR brake) were considered. The approximate BH polynomial curve polynomial curve (Budynas, Nisbett, 2011) is given by

\[ B = -10^{-11}H^2 + 6 \times 10^{-6}H + 0.156 \]  

(2)

The magnetic field intensity (\( H=NI/2h \)) of the MR fluid is in kA/m. The estimated values of torque using equation (1) and experimentally predicted values of torque are plotted in the figure 5. From this figure, huge difference between the experimental and theoretical values as a function of operating speed is observed. In the following section the reason for the deviation in torque values has been detailed.
3. Results and Discussion

To investigate the reason for the variation of the torque, the original setup was modified (as shown in figure 6) to measure the displacement of the disk using proximity sensor.

The deflection data measured at various speeds using the proximity sensor are plotted in figure 7. From this figure it can be observed the lateral deflection of rotating disc is varying between 0.1 mm to 0.18mm. In theoretical calculations, it is assumed that there will not be any lateral deflection of the disc. To reduce the vibration of the system rubber padding (isolation) was provided as shown in figure 8.

In the addition to installing rubber pads, the need to re-grease the bearings was identified. The grease of ball bearing had become black in color (probably due to impurities) as shown in figure 9(a). After completely de-greasing the bearing, the new lithium based grease was applied as shown in figure 9(b).

After using the rubber padding and reapplying the grease in the bearing, the displacement signals were measured. The results are plotted in figure 10. From this figure it can be observed that the vibration of the signal has reduced to great extent, hence proving the rubber pad (isolation) and greasing are necessary for MR brake system.

From figure 10 it is observed that the vibration (deflection) is the maximum at 300-400 RPM. To
investigate the reason for such low natural frequency, theoretical study was performed using Dunkerley’s method (Budynas, Nisbett, 2011). This method estimates fundamental critical speed of shaft carrying a number of components (gears (Shah, Hirani, 2014, Hirani 2009), pulley, coupling, etc). The system is divided into number of subsystems based on components. Using this method critical speed of each individual subsystem is estimate by direct formula. To implement this formula, a block diagram of the MR brake system is shown in figure 11.

![Fig. 11 Subsystems and components of MR brake test setup](image)

In the present system there are total five subsystems. The subsystems 3 is expected to provide more vibration and to reduce the critical speed due to the load of flywheel. To estimate the critical frequency of this subsystem (Fig. 12) following equation is used.

\[
 f_n = \frac{1}{2\pi} \sqrt{\frac{K}{M}} 
\]

Where; \( K = \frac{P}{\delta} \) and \( \delta = \frac{P l^3}{48 E I} \Rightarrow K = 48 E I \left(\frac{1}{l^3}\right) \)

and \( f_n = \frac{1}{2\pi} \sqrt{\frac{48 E I}{l^3}} \Rightarrow f_n = \frac{1}{2\pi} \sqrt{\frac{48 E I}{2 M l^3}} \)

\[
 f_n = 1.0514 \times 10^3 \text{rad} / \text{sec} \Rightarrow f_n = 167.27 \text{Hz}
\]

![Fig. 12 Free body diagram of sub system 3](image)

The estimated natural frequency of the sub system 3 (\( \omega_3 \)) using the equation (3) is 167.27 Hz which is very high compared to the natural frequency occurred in the experimental setup (6.67Hz). This indicates that the subsystem 3 is not the reason for providing low natural frequency. The theoretical study was extended to subsystem 4, consisting a low bending stiffness (can be observed from figure 13) spiral coupling.

![Fig. 13 Failure of Spiral coupling](image)

Due to the low bending stiffness subsystem makes it a weak link. A block diagram of the subsystem 4 is shown in figure 14. The critical frequency estimated for the subsystem 4 having spiral coupling of dimension 60mm length and 40mm diameter, Young’s modulus of 10MPa is 9.13Hz.

![Fig. 14 Block diagram of subsystem 4](image)

Hence from this theoretical study it is concluded that the spiral coupling has reduced the natural frequency of the system. Hence for any system the spiral coupling should not be used or if it is used then the system must be operated lesser the estimated critical speed or appropriate damping system must be provided to reduce the vibration.

Conclusion

To evaluate the performance of the MR brake, a test setup was developed and experiments were performed to measure the frictional torque. The comparison in the theoretical and experimental values of frictional torque revealed errors. Detailed theoretical and experimental investigations were performed and it was found the higher system vibration was the reason for such deviations. The vibration in the system is reduced by

- By providing isolation using rubber padding between the system and foundation
- Application of proper greasing on the ball bearings.
- Replacing the spiral coupling with rigid coupling.
